MUCH. CONSULTING · BOARDROOM TEARDOWN SIMULATION

Taking the System Apart

A simulated adversarial teardown of the handed-over demonstration system — four decision-makers, each trying to break the claim, and what the live system answers

Prepared by Waqas Abbas Mian · Senior ERP Solution Architect — grounded in the executed regression pass

The premise

Assume the demonstration system has been handed over and four sceptical people are in a room with it open, trying to take it apart — not to admire it, but to find where it is theatre. Each probe below is the hardest version of their question; each answer is what the **live system** shows, cross-referenced to the regression evidence (RT-nn). This is the teardown rehearsed before it happens for real.

1 · The sceptical CIO — "Show me it's enforcement, not decoration"

> **THE PROBE**
>
> *"Every vendor demo has a nice screen that says 'compliant'. How do I know these controls actually stop anything, rather than just displaying a badge? Turn one off and show me."*

What the system answers. The controls are not fields or badges — they are four active server-action automations whose code refuses the transaction (Regression §4, read verbatim from the live instance). The proof pattern is refusal: an expired-physician order stays **draft** because confirmation raises and rolls back (RT-05); a held lot cannot leave quarantine while its date is future (RT-06); a 50/50 tray cannot dispatch (RT-07). A control that has never refused anything is just a setting — every one of these has a refusal on record. And the 90-day hold was watched firing **live** on a fresh lot during the regression pass (RT-04), auto-stamping the date with no human touch. **Verdict: enforcement, and the code is on the table.**

2 · The QA / Regulatory lead — "Prove the audit story holds under inspection"

> **THE PROBE**
>
> *"I answer to a notified body. Can anyone delete a lot or edit history? Where's the retention? And don't tell me Odoo has native dual-signature e-sig, because it doesn't."*

What the system answers. Critical models (lot, quality check, journal entry) run archive-only — no hard-delete path inside the validated boundary — over timestamped, attributed chatter and field tracking (RT-16). Quality checks are recorded, attributed and passed at their control points (RT-18). And the honesty is the credibility: the design does **not** claim native dual-authentication e-signature, because Odoo has none — it is a designed two-step release gate at GAMP Category 5, stated as such in the validation plan. A partner who claimed the native feature would fail the first audit; naming the boundary is what survives one. **Verdict: the audit story is structural, and the one platform gap is declared, not hidden.**

3 · The CFO — "The money has to be real"

> **THE PROBE**
>
> *"Consignment stock at a hospital — is it on my balance sheet or not? And you claim multi-payer invoicing; show me it's real and not a slide."*

What the system answers. The consigned implant (SN-HC-0002) sits physically at Klinikum München but is valued **€1,200 on MDR's books** at an internal-typed location (RT-10) — the ledger tells the accounting truth of consignment. The posted invoice (€4,850) carries a 100% distribution across all three analytic plans on one line (RT-11) — the spine that ties every payer document to the clinical event. On multi-payer: the design is explicit that a sale order natively invoices one partner, so **payer-split invoicing is named extension scope, not claimed as native** — the analytic spine those splits reconcile through is what is demonstrated. **Verdict: the demonstrated money is real and on the ledger; the extension is scoped honestly.**

4 · The hostile much. technical reviewer — "I build Odoo for a living; I'll find the soft spots"

> **THE PROBE**
>
> *"This is Studio config — it won't survive an upgrade. Your API confirm throws an error. There are stray draft invoices. Field Service is 'simulated'. Pick any of those apart."*

THE JAB	THE STRAIGHT ANSWER
"Studio won't survive upgrades."	Studio fields and automations carry forward as data far better than external modules — but the plan doesn't assume zero-touch: it budgets a delta-assessment and re-runs the TC-01…TC-19 regression on every release candidate. Managed, not hoped.
"Your API order-confirm throws an error."	Correct, and it is a trial-tenant XML-RPC compute quirk, reproduced and documented — the browser UI confirms fine (that is how S00002/S00004 are in a confirmed state), and it never reaches the gate logic, which is verified active in code. It is a tenant characteristic, not a solution defect.
"Stray draft invoices."	Two unposted drafts downstream of a confirmed order — expected, outside the posted-invoice path, and touching no compliance claim. Noted in the regression report rather than quietly left.
"Field Service is simulated."	Declared, not disguised — the tier lacks the app, so the surgery-consumption trigger was run as an inventory move and labelled SIMULATED in the UAT. Production uses the FSM event. One honest cell buys the other fifteen their credibility.

Verdict: every soft spot the reviewer names is already named in the package, with a mechanism or an honest boundary attached. Nothing in the teardown surfaced a claim the system cannot stand behind.

> **WHAT THE TEARDOWN PROVES**
>
> The system survives being taken apart because it was built to be taken apart: the controls refuse in code, the money is on the ledger, the audit trail is structural, and every boundary is declared before it can be discovered. The strongest thing a candidate can hand a room is a system that gets *more* convincing the harder it is pushed — because the honesty was engineered in, not applied afterwards.
