

# Pitch Simulation & Readiness Report: Global QA Audit

Odoo ERP Enterprise Architecture & Pitch Package — MDR Devices Medizintechnik GmbH

HIRING ENTITY

much. Consulting

PANEL

MDR Devices CEO · MDR Devices CIO · much. Consulting Managing Partner

SECTION 1 · MARKET & CONSULTING VIABILITY INDEX

| DRIVER                                                                                                               | EFFECT ON POW |
|----------------------------------------------------------------------------------------------------------------------|---------------|
| Technical architecture is internally consistent and matches verified Odoo behavior (post-correction pass)            | +12%          |
| Explicit native/extension split mirrors much. Consulting's actual published methodology — signals real firm research | +15%          |
| No generic AI-fluff language detected in copy or script                                                              | +5%           |
| Closing ask (Slide 12) is commercially soft — no fixed scope, fee, or signature mechanism                            | -8%           |
| Multi-tier payer reconciliation limitation still oversold in current documents (see Section 2/3)                     | -6%           |
| Two structural process gaps — reverse logistics and reusable-instrument sterilization — entirely unaddressed         | -10%          |
| Rebuttal quality on the hardest objections (upgrade validation, e-signature) is genuinely strong and specific        | +10%          |

**Net: 68%.** This is a credible, above-average candidate pitch — not yet a “won” pitch. The gap between 68% and a defensible 85%+ is closeable in the 24-hour window below, not a fundamental rebuild.

**Hiring Panel Score: 7/10** for a Principal Architect seat. The technical grounding and self-correction discipline (visible in the audit trail this package now carries) are exactly what a Principal-level hire should demonstrate. What is missing for an 8+ is command of the close and the two gaps flagged in Section 4 — a Principal is expected to have already caught reverse logistics and reprocessing loops without being asked, since those are standard MedTech operational realities, not edge cases.

## The “Fluff” Liquidation Audit

A full pattern scan (seamless, leverage, unlock, synergy, cutting-edge, robust, holistic, empower, best-in-class, paradigm) returned **zero matches** across all seven source documents. That is a genuinely clean result — most AI-generated consulting copy fails this test immediately. Three softer weaknesses remain, and an unforgiving panel will still catch them:

| LOCATION                  | AS WRITTEN                                                       | PROBLEM                                                                                                                                                                                               | REWRITE                                                                                                                                                                                                                                   |
|---------------------------|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slide 12 / Memo close     | "Four phases. One validated thread. A decision point next week." | Vague — no committed scope, fee, or date; sounds confident but commits to nothing a CFO can put in a calendar                                                                                         | "Sign off on a fixed-fee three-week discovery sprint by [date]. You'll see Sales and Quality configuration live in your own sandbox before the next board cycle."                                                                         |
| Memo / Script (recurring) | "the direction is consistent" / "the direction holds"            | Used verbatim in two separate documents to hedge unquantified estimates — repetition across documents from the same author reads as a stock phrase, not a considered judgment                         | Vary the hedge per document: memo — "we'd expect a comparable order of magnitude, confirmed during discovery"; script — spoken naturally, drop the phrase entirely and just say "we'll know the real number once we've seen your volumes" |
| Slide 4 / Script          | "One data model. One audit trail. One definition of compliant"   | Strong written copy, but a rule-of-three delivered identically in both the deck text and the spoken script risks sounding recited rather than spoken, if delivered without deliberate vocal variation | Keep the line on the slide as written; in the spoken delivery, paraphrase slightly ("one model, one trail, one definition everyone actually shares") so it doesn't sound read off the slide behind the presenter                          |

## SECTION 2 • BOARDROOM INTERROGATION SIMULATION

### Q1 Working Capital Objection

CEO

*"A mandatory three-month hold on every raw material lot ties up cash before we've sold a single implant. What's that actually costing me, and why should I accept it?"*

#### CANDIDATE RESPONSE

"It's costing you real working capital — I won't minimize that. What it's not costing you is discretion: the ninety-day hold is a regulatory floor, not a design choice we can trade away. What we control is how tightly we plan around it. Reordering rules trigger off post-hold available stock, not gross on-hand stock, so the hold is priced into your replenishment cadence from day one instead of surfacing as a surprise cash gap at go-live. I'd want your actual raw material consumption rates in discovery to size the exact number — but the honest framing is: this is a cost of compliance you already carry informally today, we're just making it visible and plannable instead of absorbing it as unplanned variance."

### Q2 Custom Code vs. Upgrade Validation Trap

CIO

*"Every SaaS vendor promises upgrades are painless. How does this system stay in a validated GxP state through an Odoo version upgrade without us paying for a re-validation project every eighteen months?"*

#### CANDIDATE RESPONSE

"It doesn't stay validated for free — nobody can honestly promise that, and I'd be worried if a vendor did. What changes the cost profile is scope. The native core — credential gating, quarantine automation, analytic billing — is Studio configuration, and Studio changes carry forward through Odoo's upgrade path as data, not as code that has to be manually ported. That review is real but small. The one place true re-validation effort concentrates is the extension layer — the UDI reporting structure and the QA release gate — which we've deliberately scoped down to the smallest possible footprint and validated separately at Category 5 rigor precisely so that's the only place your recurring cost lives. You're not paying to re-validate everything. You're paying to re-validate a small, named, budgeted piece."

Q3 Odoo Constraint Challenge — Multi-Tier Payer Reconciliation

MUCH. CONSULTING PARTNER

“Walk me through what happens when a claim has to split across a primary insurer, a secondary insurer, and a patient co-pay, with a vendor rebate netting against the same event. Does native Odoo actually do that?”

CANDIDATE RESPONSE

“Honestly — not on its own, and I want to be precise about where the line sits. Native Odoo’s partial invoicing policy and multi-dimensional analytics handle a clean two-way split well: insurer and patient, one shared analytic key. A genuine multi-tier waterfall — primary insurer, secondary insurer, patient balance, and rebate netting all reconciling against one clinical event — is claims adjudication logic, and that’s outside what Odoo’s accounting engine does out of the box. That’s exactly the kind of requirement that belongs in the scoped extension layer, not something I’d claim native Odoo solves. I’d rather tell you that plainly now than have it surface as a gap during UAT.”

Q4 Change Resistance

CEO

“My surgical field teams are used to working a certain way. What happens the first time this system blocks someone in the middle of scheduling a surgery?”

CANDIDATE RESPONSE

“That’s the scenario we design around directly, not after the fact. Credential and quarantine blocks are validated in discovery against your actual current data — expired certifications, stock genuinely still on hold — so a live block reflects a real compliance state, not a data quality problem we created. Before go-live, every field team sees their own data pass cleanly through the new gates in a test environment, so the first time they encounter a block in production, it’s not a surprise, it’s confirmation the system caught something worth catching.”

Q5 Legacy Data Cutover

CIO

“We have open device history records and active complaints sitting in the current QMS and LIMS today. What happens to that history on cutover day?”

CANDIDATE RESPONSE

“That’s a discovery-phase deliverable, not a go-live afterthought — open records don’t get abandoned, and I’d flag it as a red flag if a proposal didn’t address it. Closed, historical lots migrate as reference data. Open device history records and active complaints run in a defined parallel-operation window, closed out in the legacy system before their thread transfers, so nothing active gets orphaned mid-record. I’d rather scope that cutover plan explicitly in Phase 1 than have it discovered as a gap in week six.”

SECTION 3 · CORE COMPLIANCE & REASONING VALIDATION MATRIX

| CORE REQUIREMENT     | PROPOSED ARCHITECTURE / FIELD MAPPING                                                                                                                                    | REGULATORY VIABILITY                                           | TECHNICAL VULNERABILITY / REAL-WORLD EDGE CASE                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MDR/UDI Traceability | <code>stock.lot</code> (renamed from <code>stock.production.lot</code> in Odoo 16) — native GS1 parsing into DI, plus extension-layer sub-fields for batch/serial/expiry | <div>PASS</div> conditional on extension layer being delivered | Native GS1 nomenclature handles standard Application Identifier-formatted barcodes cleanly. Edge case: hospitals frequently re-label incoming devices with proprietary internal tracking labels that do not conform to GS1 structure — these will not auto-parse and need a manual-entry fallback path, which is currently undocumented in the package. |

| CORE REQUIREMENT      | PROPOSED ARCHITECTURE / FIELD MAPPING                                                                                                                                                                                                                                                                                           | REGULATORY VIABILITY                                                         | TECHNICAL VULNERABILITY / REAL-WORLD EDGE CASE                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-Month Quality Hold  | (Correction to submitted mapping) — not implemented via Reordering Rules. Actual mechanism: Quality Control Point (native Quality app) + push-rule routing to a quarantine location + scheduled action gating release on elapsed hold and check-pass. Reordering Rules only govern replenishment timing downstream of the hold. | <b>AT RISK</b> as originally labeled; <b>PASS</b> with the corrected mapping | The real vulnerability isn't the hold itself, it's a boundary condition: a lot that fails its Quality Check <i>after</i> the 90-day timer has already elapsed needs a disposition path (scrap, return-to-vendor, extended hold) that is not currently modeled — right now the spec only describes the "pass + timer elapsed" happy path.                                                                                                          |
| Physician Gatekeeping | <code>res.partner</code> credential fields + automated action blocking<br><code>sale.action_confirm()</code>                                                                                                                                                                                                                    | <b>PASS</b>                                                                  | The block logic is technically a small server action override — that is a sliver of custom logic, not literally zero code, and should be named as such rather than folded into "no custom development" claims elsewhere in the deck. Edge case: locum or visiting physicians without an existing <code>res.partner</code> record at time of order — the block needs a defined "pending verification" state, not just validated/expired/suspended. |
| Multi-Stage Claims    | <code>account.move</code> + multi-dimensional analytic accounting                                                                                                                                                                                                                                                               | <b>AT RISK</b>                                                               | Confirmed in Section 2, Q3: native Odoo handles a clean two-party split well but does not perform true multi-tier claims adjudication (3+ payers with rebate netting) out of the box. Current package documents this honestly in the rebuttal playbook but has <b>not yet updated</b> the core architecture doc or memo to reflect that this specific requirement sits in the extension layer — this is an open action item, not yet closed.      |

## SECTION 4 • GAP ANALYSIS & FINAL REFINEMENT ROADMAP

### Critical Operational Gaps (Unaddressed)

- Reverse logistics for defective or expired consignment stock.** The value stream models a one-way flow — supplier to patient. No stage documents what happens when a hospital returns unused, expired, or damaged consignment stock to MDR Devices: does it re-enter quarantine, get scrapped, trigger a credit note against the original consignment record? A real client will ask this in the first ten minutes.
- Reusable surgical instrument tray sterilization cycles.** The entire architecture assumes single-use, one-way consumption (implant → consumed). Surgical instrument kits are reusable assets that cycle through use → return → sterilization → return-to-stock repeatedly, with their own validation requirement (autoclave cycle logs, sterility re-certification per cycle). This is a structurally different inventory pattern — an asset loop, not a consumption event — and the current package does not model it at all despite the case study explicitly naming "surgical instruments" alongside implants.
- Legacy data cutover for open records.** Addressed verbally in Section 2, Q5, but not yet written into any deliverable. Open device history records, active complaints, and in-flight CAPAs in the current QMS/LIMS need an explicit parallel-run and cutover plan — currently absent from every document in the package.

### The 24-Hour Execution Blueprint

- ☐ Rewrite the Slide 12 / memo close to a specific, committed ask — fixed scope, fixed fee framing, a real date — per Section 1's rewrite.
- ☐ Update the Object Schema doc and memo to explicitly place multi-tier payer reconciliation (3+ payers, rebate netting) inside the named extension layer — currently only the rebuttal playbook says this; the architecture docs still imply native Odoo alone handles it.
- ☐ Add one paragraph each, in the Value Stream doc, for: (a) reverse consignment returns, (b) reusable instrument sterilization loop, (c) legacy data cutover — even a scoped "addressed in discovery, pattern below" is sufficient; silence on all three is the real risk.
- ☐ Correct the Quality Hold field mapping — replace any remaining "Reordering Rules" framing with Quality Control Point + push rule + scheduled action, and add the fail-after-hold-elapsed disposition path.

- ☐ Rehearse Q1-Q5 above out loud, twice, at full pace — not read silently. The multi-tier payer answer (Q3) is the one most likely to be delivered too defensively; practice saying “not on its own” with confidence, not apology.
- ☐ Time the full 12-slide run at conversational pace against a stopwatch — confirm it lands at 18–20 minutes, leaving genuine room for the interrogation.
- ☐ Memorize the Slide 5 pivot line verbatim — it is the single moment in the deck that proves firm-specific research, and it is worth over-preparing relative to its length.
